# Motivation & definitions

# Primordial matter in heavy-ion collisions

- **Quark-Gluon Plasma (QGP) research**

# Primordial matter in heavy-ion collisions

- **QGP in experimental vs theory points**

- By colliding heavy-ions we can form small drop of the hot & dense primordial matter
- No direct observations, just **signatures**: jet-quenching, correlations, collective effects, **(anisotropic) flow...**
- Need a complex description, including QCD phenomenology, hydrodynamics, (non-equilibrium) thermodynamics

# Flow ( $v_n$ ) in heavy-ion collisions

- **Experimental point:**
  - Flow describes the azimuthal momentum space anisotropy of particle emission for a non-central heavy-ion collision.

# Flow ( $v_n$ ) in heavy-ion collisions

- **Experimental point:**

- Flow describes the azimuthal momentum space anisotropy of particle emission for a non-central heavy-ion collision.
- The  $n^{\text{th}}$  harmonic coefficient of the Fourier expansion of azimuthal momentum distribution:

$$E \frac{d^3N}{dp^3} = \frac{d^2N}{p_T dp_T dy} \frac{1}{2\pi} \left( 1 + 2 \sum_{n=1}^{\infty} v_n \cos[n(\phi - \psi_n)] \right)$$

# Flow ( $v_n$ ) in heavy-ion collisions

- **Experimental point:**

- Flow describes the azimuthal momentum space anisotropy of particle emission for a non-central heavy-ion collision.
- The  $n^{\text{th}}$  harmonic coefficient of the Fourier expansion of azimuthal momentum distribution:

$$E \frac{d^3N}{dp^3} = \frac{d^2N}{p_T dp_T dy} \frac{1}{2\pi} \left( 1 + 2 \sum_{n=1}^{\infty} v_n \cos[n(\phi - \psi_n)] \right)$$

- The  $v_2(p_T, y) = \langle \cos(2(\phi - \psi_2)) \rangle$  directly reflects the initial spatial anisotropy of the nuclear overlap region in the transverse plane.

# Flow ( $v_n$ ) in heavy-ion collisions

- Experimental point:**

- Flow describes the azimuthal momentum space anisotropy of particle emission for a non-central heavy-ion collision.
- The  $n^{\text{th}}$  harmonic coefficient of the Fourier expansion of azimuthal momentum distribution:

$$E \frac{d^3N}{dp^3} = \frac{d^2N}{p_T dp_T dy} \frac{1}{2\pi} \left( 1 + 2 \sum_{n=1}^{\infty} v_n \cos[n(\phi - \psi_n)] \right)$$

- The  $v_2(p_T, y) = \langle \cos(2(\phi - \psi_2)) \rangle$  directly reflects the initial spatial anisotropy of the nuclear overlap region in the transverse plane.
- Higher flow components can be measured

# Future Nuclear Collisions at LHC

- **LHC Schedule with new nuclear collisions**

- Run 2: XeXe
- Run 3: pO & OO

# Future Nuclear Collisions at LHC

- **LHC Schedule with new nuclear collisions**

- Run 2: XeXe
- Run 3: pO & OO

# Nuclei & nuclear structure

# Nuclei for Future Nuclear Collisions

- **High-mass and deformed nuclei are in the focus:**

# Nuclei for Future Nuclear Collisions

- **Experimental possibilities & interest**
  - Large deformed nuclei: uranium, gold, xenon
  - Smaller zirconium, rubidium, oxygen, neon

# Nuclei for Future Nuclear Collisions

- **Oxygen and Neon are unique**
  - Oxygen is a double magic nucleus, since both shells are closed shell. In cluster model Tetrahedron shape.
  - Neon, has bowling pin shape, even more complicated geometry

# The shape of the oxygen

## Modeling the oxygen

- **Woods-Saxon (WS)**

$$\rho(r) = \rho_0 \left[ 1 + \alpha \left( \frac{r}{a} \right)^2 \right] \exp\left( \frac{-r^2}{a^2} \right)$$

- **Harmonic oscillator (HO)**

$$\rho(r) = \frac{\rho_0 (1 + w \left( \frac{r}{r_0} \right)^2)}{1 + \exp\left( \frac{r-r_0}{a} \right)}$$

- **Normalization:**

$$\int \rho(r) d^3r = 4\pi \int \rho(r) r^2 dr = Ze$$

# The shape of the oxygen

## Nuclear structure description

– Cluster model vs.

Non-cluster model (Woods-Saxon)

● Proton    ● Neutron    ●  $\alpha$  -particle

$\alpha$  - clustered Oxygen ( $^{16}\text{O}$ ) nucleus

● Proton    ● Neutron

Non-clustered Oxygen ( $^{16}\text{O}$ ) nucleus

# Calculating the flow in small systems

# Calculating the flow

## Event plane and average method

$$v_n = \langle \cos[n(\phi - \psi_n)] \rangle$$

- Need to determine the event plane, which fails for small nuclei:

# The Model

- **A full hydro & Boltzmann transport with viscosity:**

- IPGlasma
- MUSIC
- iSS
- URQMD

$$\langle 2 \rangle = \frac{|Q_n|^2 - M}{M(M-1)},$$

$$\langle 4 \rangle = \frac{|Q_n|^4 + |Q_{2n}|^2 - 2 \cdot \text{Re}[Q_{2n} Q_n^* Q_n^*]}{M(M-1)(M-2)(M-3)} - 2 \frac{2(M-2) \cdot |Q_n|^2 - M(M-3)}{M(M-1)(M-2)},$$

$$c_n\{2\} = \langle \langle 2 \rangle \rangle,$$

$$c_n\{4\} = \langle \langle 4 \rangle \rangle - 2 \cdot \langle \langle 2 \rangle \rangle^2.$$

$$v_n\{2\} = \sqrt{c_n\{2\}},$$

$$v_n\{4\} = \sqrt[4]{-c_n\{4\}}.$$

- **Kinematical settings are:**

- Energy (c.m.): 7 TeV O+O
- Pseudorapidity:  $|\eta| < 2.5$
- Transverse momentum:  $0.2 < p_T < 5.0$  GeV/c
- Pseudorapidity gap:  $|\Delta\eta| > 1.0$

# Calculating the flow

## Event plane and average method

## Multiparticle Q-cumulant method

# Flow in oxygen-oxygen (OO)

# Flow components in O+O @ 7TeV

## 2-cummulants based calculation of $v_2$ & $v_3$

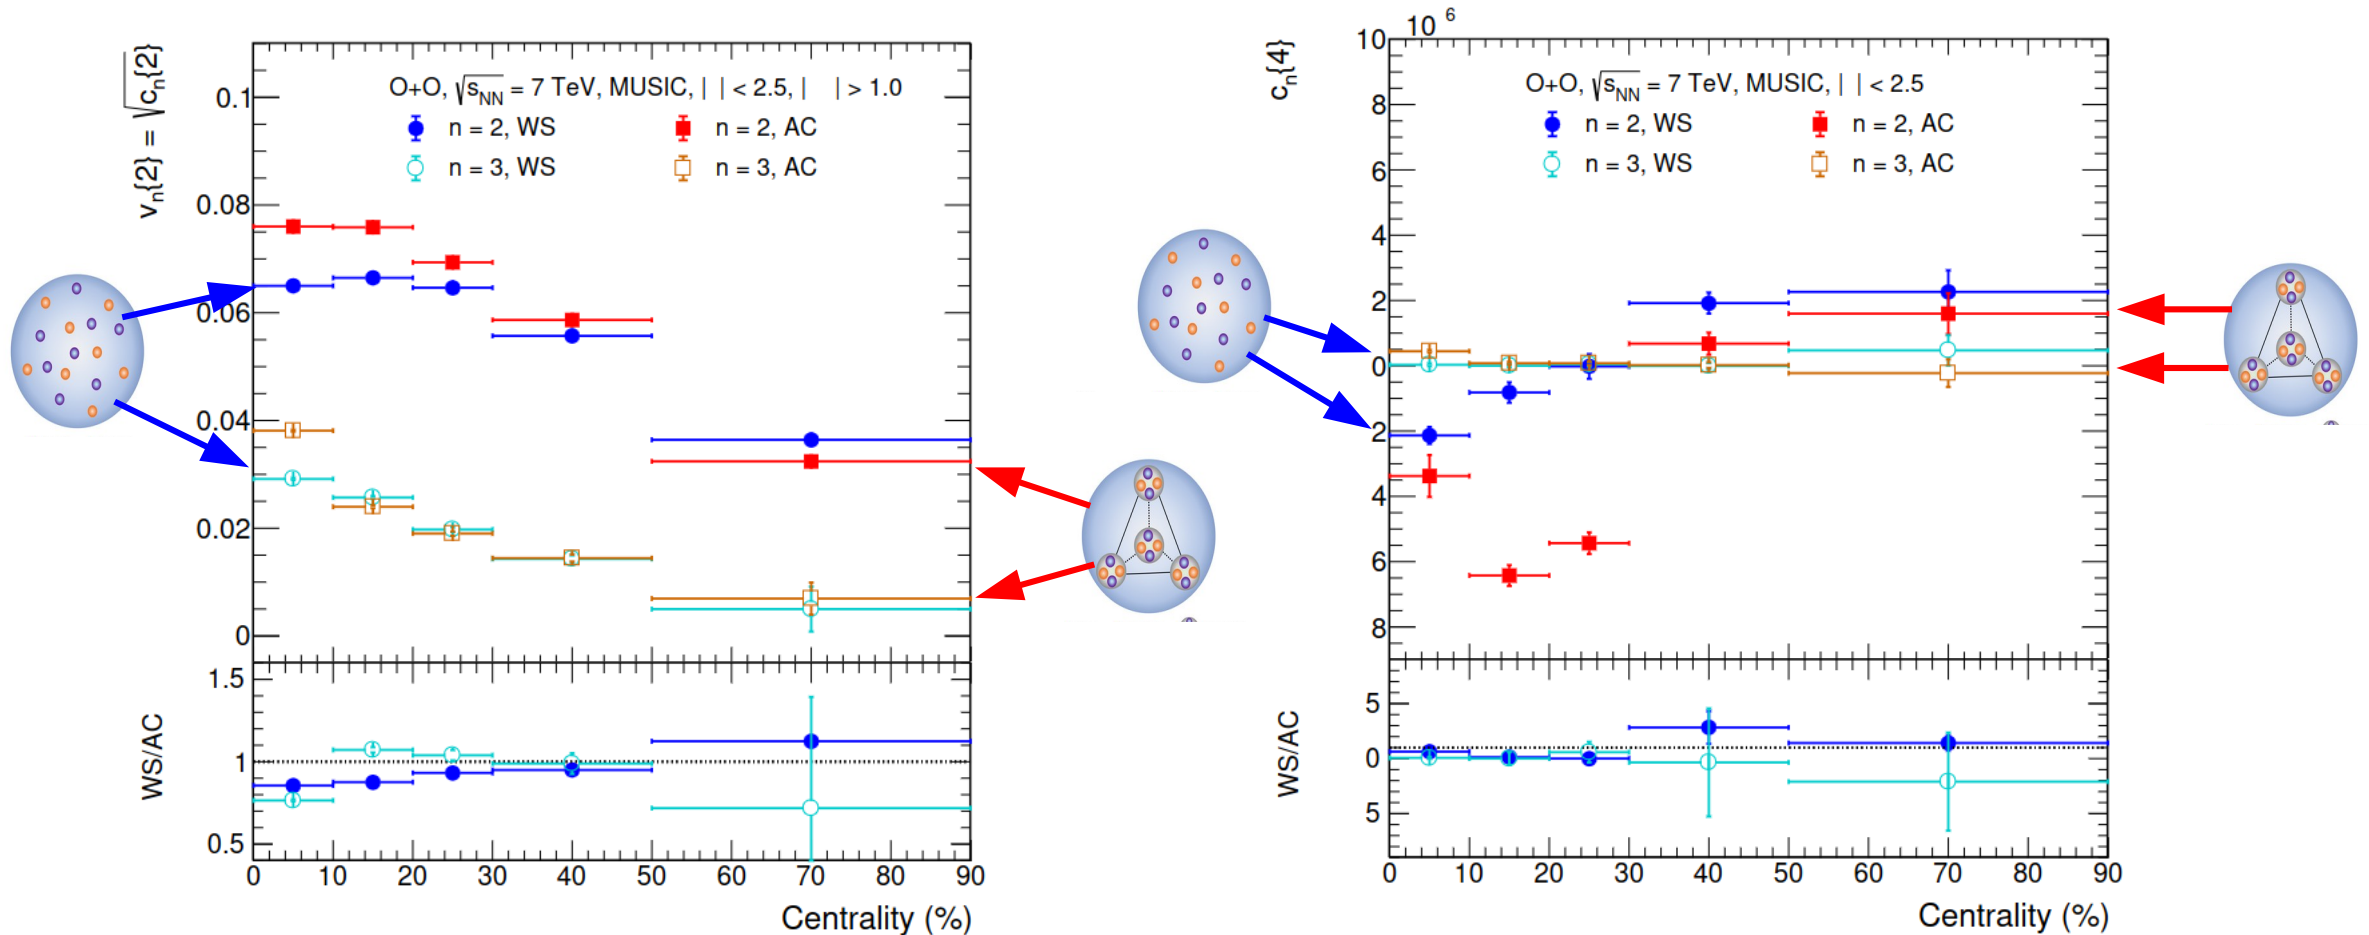

# Flow components in O+O @ 7TeV

## 2-cummulants based calculation of $v_2$ & $v_3$

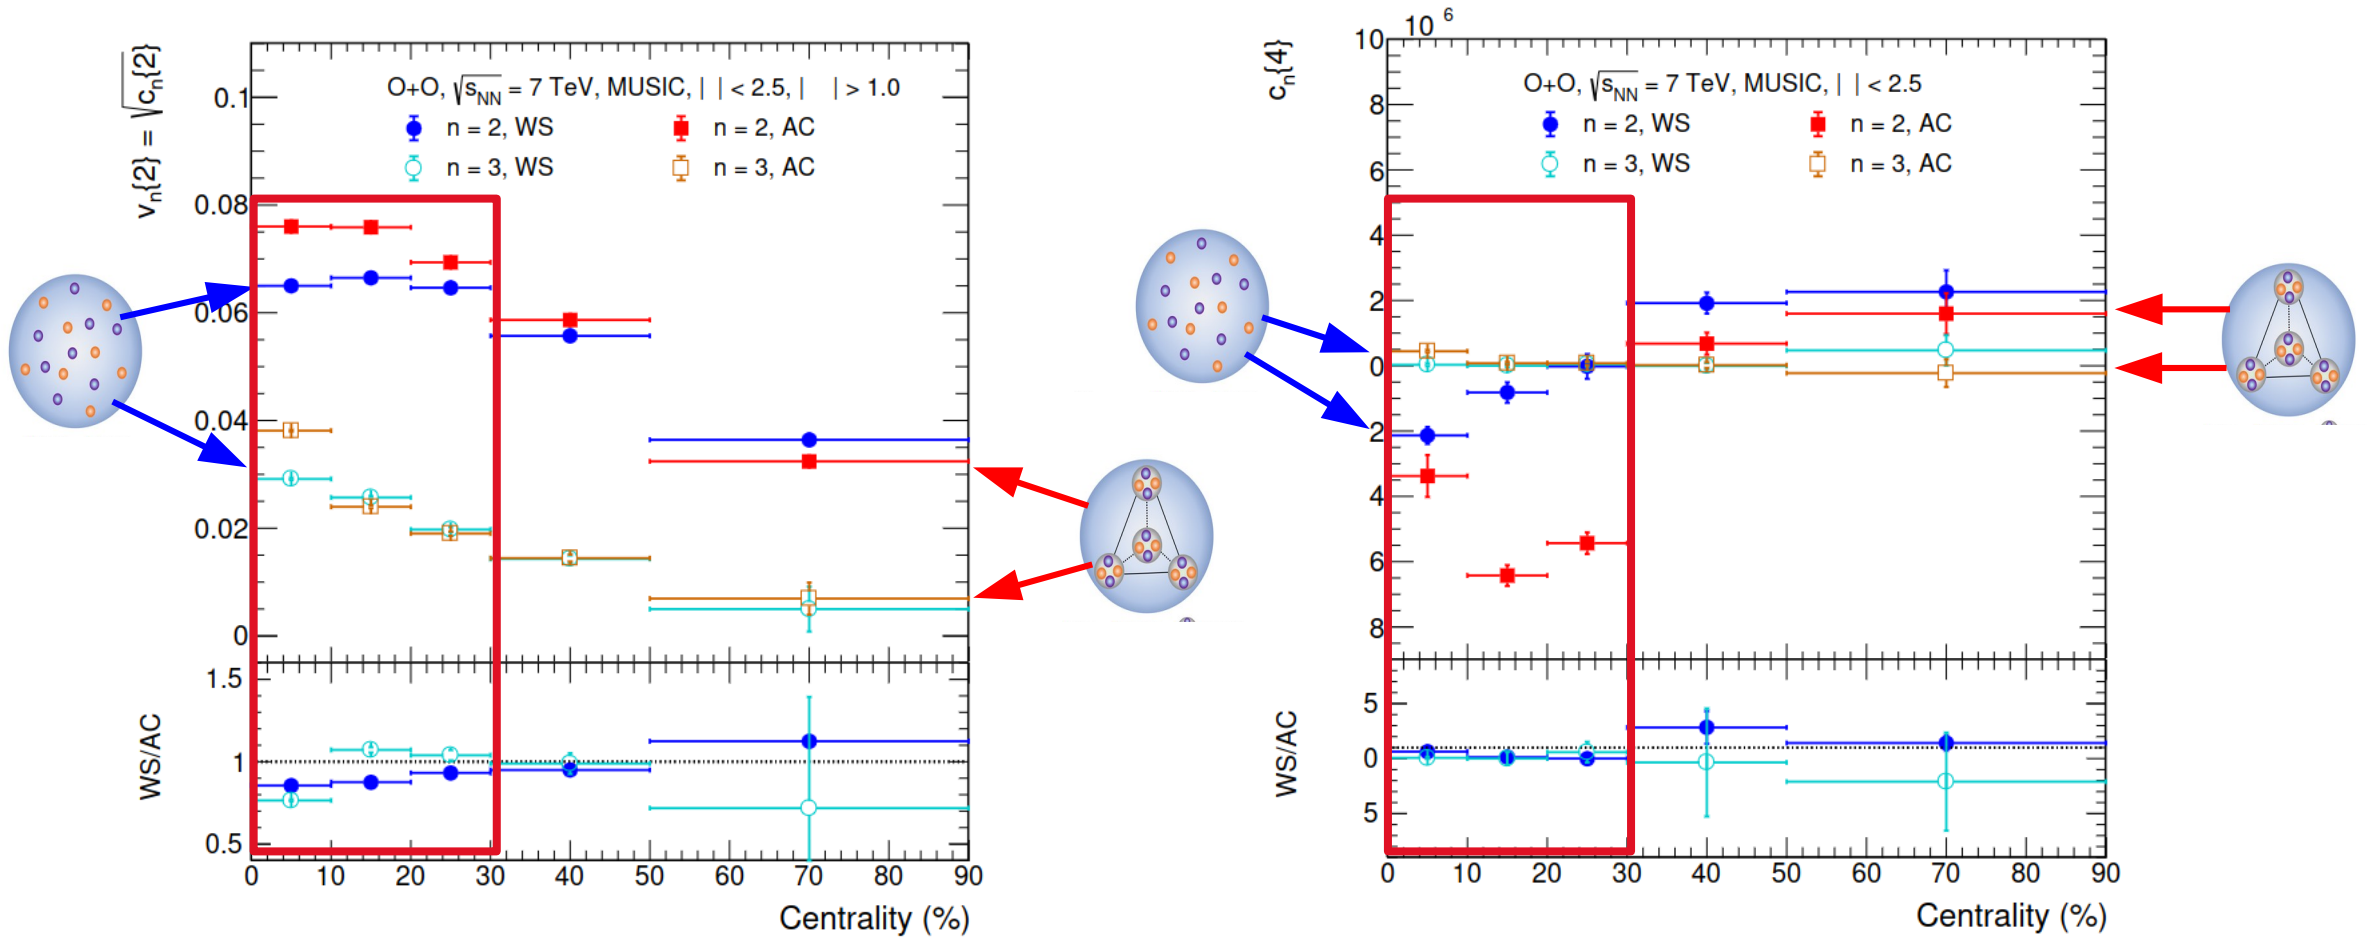

# Flow components in O+O @ 7TeV

## 2- & 4-cummulants based $v_n$ & $c_n$ calculations

# Flow components in O+O @ 7TeV

## 2- & 4-cumulants based $v_n$ & $c_n$ calculations

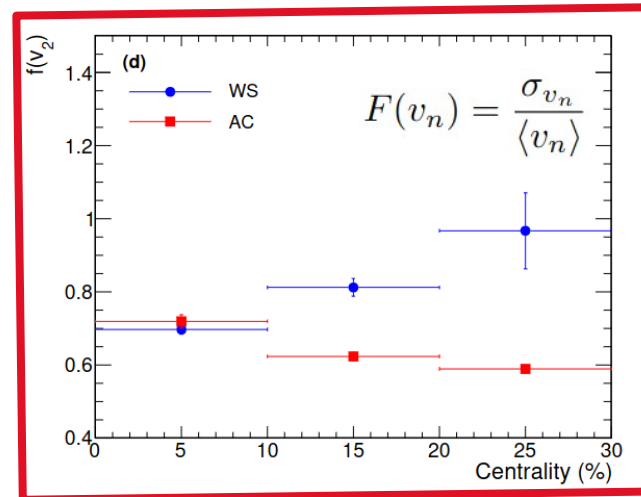

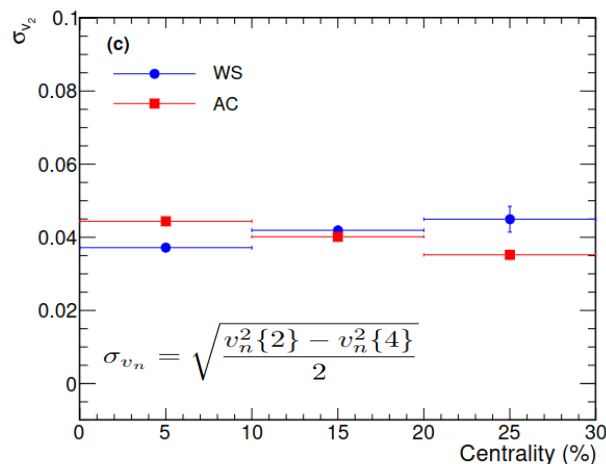

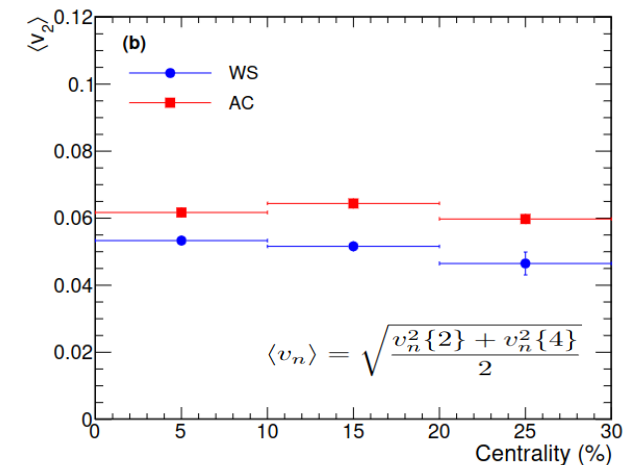

# Flow components in O+O @ 7TeV

## 2- & 4-cummulants based calculations

- Flow and fluctuation measures changed significantly in the most central 0-30% regime
- Alpha-cluster has larger values, than Wood-Saxon profile
- Higher cummulants has higher effect at larger centrality
- Clearly visible on the relative measure:

$$F(v_n) = \frac{\sigma_{v_n}}{\langle v_n \rangle}$$

# Conclusions

- **In a IPGlasma+MUSIC+iSS+URQMD = “realistic model”**
  - It is possible to calculate the flow for small system like OO
    - event plane method fails
    - 2- & 4-cummulants can be calculated for  $v_2$
    - $v_3$  can not be calculated for 4-cummulant
    - Need for a kinematical cut to reduce non-flow
- **Nuclear structure has consequences on the flow**
  - Nuclear structure matters in the calculations
    - Alpha Cluster method is stronger than Woods-Saxon
    - Relevant difference is in centra O+O collisions
    - **Comparable with the size of the alpha cluster**

**Thank You!**

Can we prove the model' validity  
in heavy-ion collisions?

# Calculating the flow

## Event plane and average method

$$v_n = \langle \cos[n(\phi - \psi_n)] \rangle$$

## Multiparticle Q-cumulant method

- Flow vector  $Q_n = \sum_{j=1}^M e^{in\phi_j}$

- The 2- and 4-particle cumulants are:

$$\langle 2 \rangle = \frac{|Q_n|^2 - M}{M(M-1)},$$

$$\langle 4 \rangle = \frac{|Q_n|^4 + |Q_{2n}|^2 - 2 \cdot \text{Re}[Q_{2n} Q_n^* Q_n^*]}{M(M-1)(M-2)(M-3)} - 2 \frac{2(M-2) \cdot |Q_n|^2 - M(M-3)}{M(M-1)(M-2)},$$

$$c_n\{2\} = \langle\langle 2 \rangle\rangle,$$

$$c_n\{4\} = \langle\langle 4 \rangle\rangle - 2 \cdot \langle\langle 2 \rangle\rangle^2.$$

$$v_n\{2\} = \sqrt{c_n\{2\}},$$
$$v_n\{4\} = \sqrt[4]{-c_n\{4\}}.$$

# Calculating the flow

## Suppressing the non-flow contribution:

- Kinematical cut: 2 sub-events, A&B are introduced, with a rapidity gap:

$$\langle 2 \rangle_{\Delta\eta} = \frac{Q_n^A \cdot Q_n^{B*}}{M_A \cdot M_B} \quad \longrightarrow \quad v_n\{2, |\Delta\eta|\}(p_T) = \frac{d_n\{2, |\Delta\eta|\}}{\sqrt{c_n\{2, |\Delta\eta|\}}}$$

- Differential flow cummulants:

$$\begin{aligned} d_n\{2\} &= \langle\langle 2' \rangle\rangle, \\ d_n\{4\} &= \langle\langle 4' \rangle\rangle - 2\langle\langle 2' \rangle\rangle\langle\langle 2 \rangle\rangle \end{aligned} \quad \longrightarrow \quad d_n\{2, |\Delta\eta|\} = \langle\langle 2' \rangle\rangle_{\Delta\eta}$$

- Mean and the fluctuations of the flow & ratio:

$$\langle v_n \rangle = \sqrt{\frac{v_n^2\{2\} + v_n^2\{4\}}{2}}$$

$$\sigma_{v_n} = \sqrt{\frac{v_n^2\{2\} - v_n^2\{4\}}{2}}$$

$$F(v_n) = \frac{\sigma_{v_n}}{\langle v_n \rangle}$$

# Flow components in O+O @ 7TeV

## 2-cummulants based $v_n(p_T)$ calculations

Centrality
